RE: GEOTECHNICAL LETTER

RESPONSE TO PEER REVIEW

PLAN CHANGE REPORT, 631 SHANDS ROAD, CHRISTCHURCH

Introduction

Soil & Rock Consultants have been asked to respond to a peer review by lan McCahon of Geotech Consulting Limited who have peer reviewed a Soil & Rock Consultants plan change geotechnical report titled "Geotechnical Investigation, proposed Rural Residential Subdivision, 631 Shands Road, Prebbleton; Rev A, Ref C15449, dated 16 October 2015". Attached to this letter is the geotechnical peer review letter.

Geotechnical Response to Peer Review

We have reviewed the peer review letter by Ian McCahon of Geotech Consulting Limited and we agree that Ian has raised some valid points as part of his review. In this section we will endeavour to provide insight into our methodology and findings.

With regards to our investigation density, we agree that the site specific testing is somewhat limited, especially considering a number of the proposed deep investigations did not achieve a sufficient investigative depth. We did not recommend further testing as a result of the insufficient testing as we considered that we had sufficient information based on our investigative information, site specific ECan well logs (See attached for plan and well log) and neighbouring deep investigations (See attached Riley Report). For the purpose of a plan change, we considered the information available to be sufficient for the purpose. We also took into account the lack of liquefaction induced surface expression and damage following the recent Christchurch earthquake sequence as well as the inferred (based on CGD information) groundwater level of over 8m depth providing a significantly thick non-liquefiable crust. We will, however, learn from the limitations of certain testing equipment used and ensure that more comprehensive and extensive site specific testing is undertaken during the subdivision consent stage of testing which will include more test pits scattered across the site as per the peer review recommendations as well as ensuring deep investigative information is achieved as per the MBIE guidelines.

Yours faithfully,

SOIL & ROCK CONSULTANTS

Dear Sir,

RE: Plan Change – Stratford – 631 Shands Rd, Prebbleton, - PC 47

Geotechnical Report Peer Review

Geotech Consulting has been asked to carry out a peer review on the geotechnical report for the proposed plan change of the property at 631 Shands Road (Lot 1 DP 53112) from Inner Plains to Living 3 zone. The report is by Soil & Rock Consultants Ltd dated 16 October 2015, for M.J. Stratford, to provide information for the proposed plan change, which if successful would allow future subdivision of the 15.98 ha property into 26 lots. In particular the peer review is to ensure compliance with the CERA guidelines for the geotechnical assessment of subdivisions.

1 Site Investigation

The report describes a site investigation (in two stages) of twelve test pits to a maximum of 2.2 m depth with associated scala penetrometer tests, and four "Dynamic Probe Super Heavy" DPSH tests to between 1.1m and 7.2m depth. The site test plans show that the test pits were carried out in 3 groups, all in the northern part of the property, and therefore really sample less than about one fifth of the whole property. The DPSH tests were made near each corner of the approximately square site, but of these three stopped at 1.1 – 1.2m depth and only one extended to any significant depth of 7.2m. Deeper information is reported from regional geology maps and two Ecan well–logs are appended to the report, although their locations are not given.

The MBIE Guidance recommends a minimum investigation density for deep investigations of 0.2 to 0.5 per hectare, with a minimum of 5 for a site of 1 ha or greater in area. For this site this indicates between 5 and 8 deep investigations. Deep investigations refer to tests to enable the characterization of the soils to a depth of at least 15m. The guidelines allow for judgement as to the number of tests and their depths if initial investigations demonstrate an absence of liquefaction potential.

We therefore have 12 test pits and one DPSH test across about 20% of the site, to a maximum depth of 2.2m, two DPSH tests near the west and south corners to 1.1m depth and one DPSH test towards the east corner to 7.2m depth, and reference to two well-logs of unknown location. In our opinion, this does not adequately characterize the soil profile under the site, nor meet the intent of the MBIE guidelines.

However, the site lies to the west of the line in the Ecan liquefaction review (2012) and therefore falls in the area where damaging liquefaction is unlikely and geotechnical investigations can in most cases be designed primarily for other geotechnical hazards, and the MBIE guidance is written around assessing liquefaction.

Although the ground conditions in this area are almost certainly gravel from a shallow depth to many metres depth, as based on our own knowledge and experience of the area, our concern is that this is not well established by the information provided in the report. We recommend that additional test pits are carried out across the 80% of the area away from the existing test pits (we suggest a minimum of five) to verify the soil types and that the refusal as encountered in the DPSH tests is gravel. In addition, the locations of the Ecan well logs referred to must be detailed so that the proximity of otherwise to the site can be assessed. It would be useful to do a wider survey of the well logs to provide more additional supporting evidence that once the gravels are encountered, they are continuous to at least 10-15m depth.

2 Subsurface Conditions

The test pits showed 0.2 - 0.3m of topsoil over sandy silt which is between 0.3m and 0.9m thick over sandy gravel. The Ecan borelogs show gravel from close to the ground surface to 20m in one and 30m in the other, before any finer grained soils are encountered. The Ecan data base indicates a ground water level of 8.5 - 10m depth; none of the tests on the site encountered ground water.

3 Liquefaction Assessment

Although the gravel dominated soils and depth to groundwater combine to make the risk of liquefaction at the site very low, it is reported that a liquefaction analysis was carried out on the DPSH data. It is unclear what water table was assumed as both 3m and 8m are reported as being used. Despite the methodology being outlined, the results of the analysis are not given, but rather that as the water table is assessed at 8m depth the site can be considered to have at least an 8m non-liquefiable crust. S&R state that "liquefaction analysis indicates that liquefaction induced ground subsidence" is within the limits for Foundation technical Category TC1, and "does not change the current designation of TC1". This last statement is incorrect. The property lies outside the residential areas and has been categorized as "rural and unmapped".

We find the S&R assessment confused, but we do accept that the liquefaction hazard is low to very low, and that an equivalent TC1 category is appropriate.

4 RMA assessment

The report concludes that there are no significant geotechnical hazards on the site and that it is suitable for subdivision from a geotechnical perspective.

5 Development recommendations

The report indicates ultimate bearing capacity of 200 kPa at 0.3m and 300 kPa below 0.4m depth on the site. We accept these as reasonable, in the area sampled with the test pits. Although there is a reasonable chance that these bearing capacities are applicable across the whole site, this cannot be assumed and additional testing will be needed to verify this.

S&R continue with comments on foundation options. These are confusing as both NZS 3604 options (suitable for TC1 land) and the MBIE enhanced concrete slab options for TC2 land are given without any differentiation or commentary. Site specific testing is recommended at design stage, with which we agree.

6 Conclusion

We accept that this site is in an area where damaging liquefaction is unlikely, and an equivalent TC1 category is appropriate. From our own knowledge of the area we also accept that the site is likely to be underlain with gravel from a shallow depth. However we perturbed by the poor distribution of site testing over the whole site, with much of the site tested only by penetrometer testing without any sampling to verify soil types, and that the deeper soil profile is not well established by the information provided in the report. Inconsistencies in parts of the report are confusing but of lesser consequence.

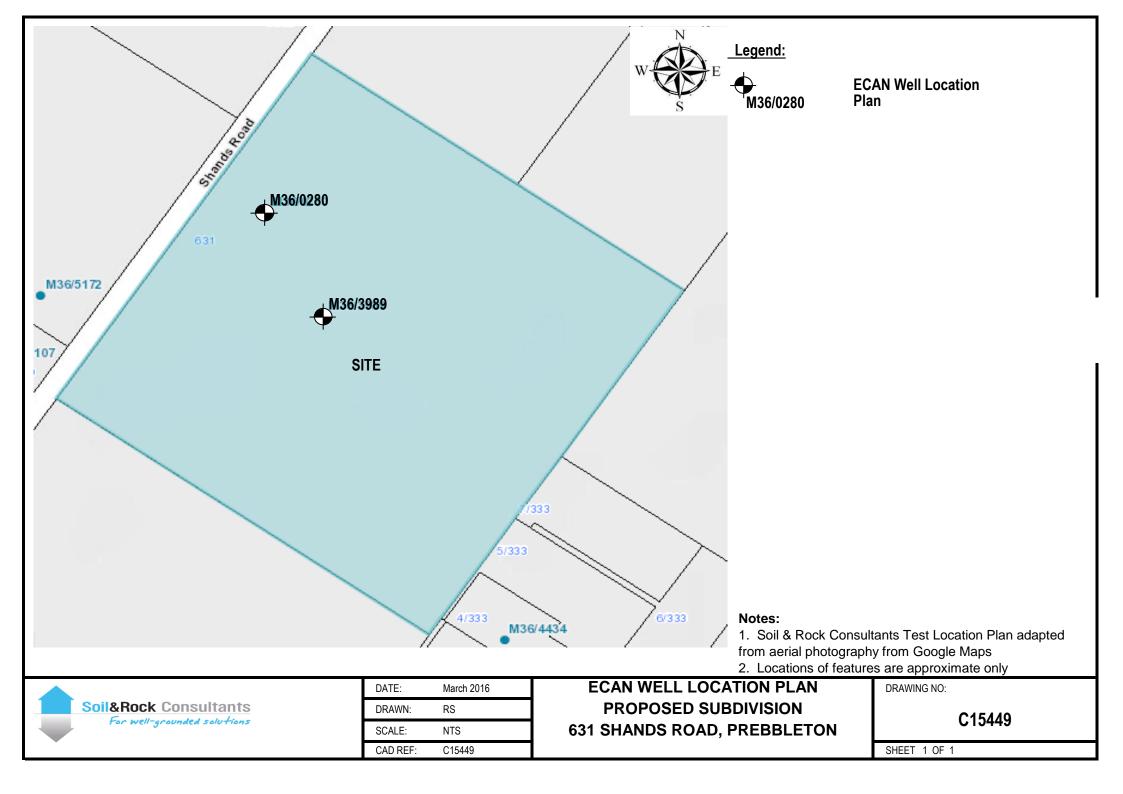

While we have recommended further testing on the site, the report is to support a plan change and thus it may be argued that additional testing can be left to a later stage. It is probably a low risk that any geotechnical issues that might adversely affect development are in fact present, but if more testing is not done now, it is important that it is at subdivision stage (if the plan change proceeds). Additional testing will also be subsequently needed at building consent stage for each building.

Yours faithfully

Geotech Consulting Limited

311 TRENTS ROAD, PREBBLETON, CANTERBURY GEOTECHNICAL ASSESSMENT FOR SUBDIVISION CONSENT

1.0 Introduction

As requested by David and Sue Anderson, via Davie Lovell-Smith Ltd, Riley Consultants Ltd (RILEY) has undertaken a geotechnical assessment for subdivision at the above property. This report is intended to provide supporting information for a subdivision consent application (by others) to subdivide the current 9.2 ha property into 16 lots, ranging in size from approximately 5,000m² to 6,100m² (refer Davie Lovell-Smith Ltd Dwg: P06845, May 2012).

The main objectives of this assessment are;

- Document geotechnical investigations undertaken by RILEY to confirm the site geology and any geological hazards potentially affecting the site.
- Comment on the likely extent and variation of the principal soil types.
- Comment on the seismic hazard and liquefaction risk, and any other geological hazards associated with the site.
- Comment on foundation options for development of the new lots.

Figure 1. Location plan – north vertical to the page and blue gridlines are 1km spaced (extract from Topo50 1:50,000 scale map, Sheet BX23 v1.02 1998).

1.1 Site Description

The property is located approximately 12.7km south-west of Christchurch city, and the property borders Trents Road and Shands Road, just outside of Prebbleton township (Figure 1 and RILEY Dwg: 12876-01). The site (Lot 2 DP 51743) is 9.2ha in size, and generally slopes gently to the southeast (ground slope estimated at 2m over 400m).

A degraded alluvial terrace, less than 1m high, trends north – south across the west of the site (Dwg: 12879-01). The site is predominantly covered with grass and local trees and shrubs. There are no nearby watercourses, although a small pond exists in the north-west of the site at the Shands Road boundary. We understand that the land has been used for horse breeding and farming since the early 1900s. This property has been subdivided from an original 440 acre block that was bound by Shands Road, Blakes Road, Springs Road, and Trents Road.

Currently there are several single storey buildings on the property, including a private residence and stables. These buildings are approximately 25 years old and are supported by a concrete slab on grade foundation system.

No evidence of land damage associated with the recent Canterbury earthquake sequence was observed at the site (i.e. to cracking or liquefaction-induced sand boils etc.).

1.2 Scope of works

The investigation has been completed in general accordance with the 'Guidelines for the Geotechnical Investigation and Assessment of Subdivisions in the Canterbury Region' released by the Department of Building and Housing (DBH) in November 2011. Specific tasks included:

- 1. Desk study of available published, publicly available, and in-house geological data.
- Walkover inspection of the site and surrounds, completed by RILEY engineering geologists on 6 and 7 November 2012 (refer RILEY Dwg: 12876-01, Appendix A).
- 3. Subsurface investigation consisting of:
 - Eight mechanically dug inspection pits to a maximum depth of 5m (completed on 7 November 2012), with associated Scala penetrometer and Clegg hammer testing.
 - The pits were logged, and photographed, by a RILEY engineering geologist in general accordance with the New Zealand Geotechnical Society Guidelines for soil description (2005). Logs and photographs are attached as Appendix B.
 - Two dynamic probe profiles (DPH3 and DPH4) that were terminated due to practical refusal at 7.5m and 4.5m depth, respectively.
 - Two infiltration tests in inspection pits TP3 and TP6 after geological legging was completed.
- 4. Assessment of geotechnical conditions and hazards and report production.

2.0 Council Requirements for Subdivision Assessment

The Department of Bullding and Housing (DBH) has recently released Guidelines for the Geotechnical Investigation and Assessment of Subdivisions in the Canterbury Region (14 September 2012). This document provides guidelines as to what is likely to be required by councils in assessing applications for plan change and subdivision consent. Key points of relevant to the proposed subdivision include:

- Appropriate geotechnical investigations shall be carried out to enable the characterisation of ground forming materials to at least 15m below ground level, unless the ground is known to be of acceptable quality from lesser depths (for example, in areas known to be underlain by competent gravels and deep groundwater profiles, or in hillside areas).
- If initial investigations demonstrate a lack of liquefaction potential then the Engineer may judge fewer test locations or shallower depths of investigation to be appropriate.

We consider that the information gathered from our desk study of regional geology provides an adequate assessment of the site geology and liquefaction risk. As such, we have not proposed any deep investigations as the regional geology indicates that there is a thick sequence of competent gravel beneath near-surface soils. This, combined with a deep groundwater table (approximately 9m below ground level) suggests that liquefaction is not a significant hazard to the site.

Geotechnical peer review for Selwyn Council (lan McCahon of Geotech Consulting Ltd) agreed that this investigation philosophy was suitable for the anticipated ground conditions.

3.0 Regional Geology and Groundwater

A review of the published geological map of the area (Christchurch QMAP, 1:250,000 scale), publicly available Canterbury Geotechnical Database information and nearby Environment Canterbury (ECan) online well logs has been completed for this geotechnical assessment. The ECan well logs for the area indicate the water level at between 7m and 11m below ground level. Well number M35/3775 was drilled on the property itself when the house and buildings were constructed and records the water level at 9.3m below ground level in July 1987.

The general geological profile of the area is:

- Topsoil (typically less than 250mm thick) consisting of loose, silty fine to medium SAND with some organics and rootlets.
- Fine sandy SILT to silty fine SAND deposited during the last glacial advance (ca. 10,000 years). This material may infill buried channels in the underlying River Alluvium.
- 'Q1a' Alluvium (totalling 100 to 300m thick). The QMAP indicates the site to be underlain by a sequence of glacial outwash alluvium associated with glacial advance and retreat in the Late Quaternary. This typically consists of moderately thick to very thick bedded gravel to sandy GRAVEL. The ECan well logs indicate that the alluvium has a minor clay content (often noted as "claybound gravel", e.g. M3/5606 and M36/4677).

 Bedrock geology to the site is likely to comprise a sequence of weakly indurated Tertiary conglomerates, limestone, and siltstone. These strata are approximately 1.5km thick beneath the site and are underlain by greywacke sandstone and siltstone bedrock correlated to the Torlesse composite terrane.

4.0 Encountered Ground Conditions and Groundwater Conditions

The encountered geology is in general accordance with that anticipated from our desktop study. Investigations identified three soil layers at the site, the characteristics of which are described below:

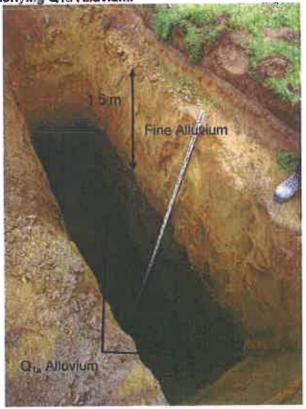

Layer 1 - Topsoil:

Topsoil is typically 0.2m to 0.25m thick, consists primarily of dark brown silty fine to medium sand with organics. This material is loose to dense from Scala penetrometer test results.

Layer 2 - Fine Alluvium:

This unit typically consists of silty SAND and underlies Topsoil. Its thickness ranges between 0.35m (TP8) and 1.6m (TP1) (Figure 2). The variable thickness reflects undulations in the ground surface, and an irregular/channelled surface in the underlying Q1a Alluvium.

The Scala penetrometer blow counts indicate variable relative densities within the layer, typically loose to medium dense (Appendix B). Clegg hammer tests were completed at selected depths in inspection pits in the Fine Alluvium. Clegg impact values (IV) from the tests are summarised in Table 1. The impact values ranges between 3 and 15, with a mean of approximately 7.

Table 1: Clegg hammer impact values (IV) in Fine Alluvium

1 A1 D14	Depth	Cleg	g Impact \	alue (IV)
Inspection Pit	(m)	test 1	test 2	test 3
TP4	0.3	8	10	10
TP4	0.6	11	11	15
TP5	0.3	9	9	10
TP5	0.6	7	7	8
TP6	0.3	9	8	9
TP6	0.6	6	5	5
TP6	0.85	4	4	3
TP6	1	3	4_	3
TP7	0.3	6	6	5
TP7	0.6	5	5	5
TP7	0.9	6	7	5

Layer 3 - Q1a Alluvium:

This unit consists of sandy GRAVEL with some to minor silt with local cobbles up to 0.2m in length. In some of the inspection pits thin sand lenses and orange (iron) and purplish black (manganese) stained lenses occur. This material is typically tightly packed with the inspection pit walls standing vertical. The dynamic probe-heavy tests were terminated early (target depth 15m) due to practical refusal. The calculated SPT N₅₀ values from the dynamic probe-heavy profiles suggest the Q1a Alluvium is dense to very dense.

Free groundwater was not encountered in any of the inspection pits; moist soils were logged from ground level. Based on ECan well logs, a minimum groundwater level of 7m below ground level is considered appropriate for the purposes of this assessment. This depth is taken as a conservative estimate from expected seasonal variability of the water level.

5.0 Geotechnical Assessment

5.1 Recorded Peak Ground Accelerations (2010 to 2011 Canterbury Earthquake Sequence)

Recorded peak ground accelerations (PGAs) for the Canterbury Earthquake Sequence have been made publicly available by GNS. A review of these PGAs from the nearest recording devices located in Templeton and Lincoln, approximately 3.5km north and 5.4km south of the of the site respectively indicate that the property is likely to have been subject to a PGA in the order of 0.9g in the Mw 7.1 September 2010 earthquake. This equates to a load exceeding the current DBH Guidelines for a design load Serviceability Limit State (SLS) earthquake (Mw 7.5). Lower PGAs were likely to have occurred for the February and June 2011 aftershocks, below the SLS design load.

5.2 Qualitative Liquefaction Risk Assessment

At least 7m of non-liquefiable/non-saturated material underlies the site as a result of the inferred minimum groundwater table. This minimised the potential for liquefaction-induced ground surface damage at the site in a Serviceability Limit State earthquake event.

Liquefaction typically occurs in recent (i.e. less than 10,000 years old), normally consolidated, and saturated (i.e. beneath the groundwater table) silt, sand and gravel. The susceptibility of a soil to liquefaction depends primarily on material density, grain size and soil composition.

Dense granular soils are generally not liquefiable (Youd et al, 1996 & 1998), and the Q1a Alluvium encountered on site is typically dense. Similar soils in Canterbury have generally performed well under recent seismic loading. No land damage was observed, and no ejected sands or lateral spreading were reported by the landowner across the site as a result of the recent Canterbury earthquake sequence.

Although no deep in situ soil tests are available for the Q1 Alluvium (or any older underlying material) it is reasonable to expect that this material is competent to considerable depth. Local looser sand and silt layers and lenses are likely to be interbedded within the gravel alluvium sequence, and these may be susceptible to liquefaction in a future design earthquake event. However, when considering the high-energy deposition environment of the alluvium these layers are likely to be relatively thin and laterally discontinuous – similar to those encountered in the inspection pits. The surrounding and everlying denser gravel is likely to minimise and bridge any local liquefaction induced settlement of these looser layers/lenses at depth (i.e. below the water table).

5.2.1 Foundation Technical Category

The Department of Building and Housing (DBH) has provided a guidance document whereby land is placed into one of three technical categories based on liquefaction deformation limits. In terms of these guidelines, we consider that the subject site is likely to be similar to those sites that fall into technical category TC1. TC1 estimated foundation settlements due to liquefaction are 15mm in an SLS earthquake event and 25mm in a ULS (Ultimate Limit State) earthquake event. The site is not likely to be subject to any lateral spreading.

5.3 Suitability of Ground for Development

It is desirable for new subdivisions on flat or gently sloping ground to provide building platforms that meet the NZS 3604 definition of "good ground", as such building platforms do not require specific engineering design of foundations for residential development. NZS 3604 defines the criteria for "good ground" as that which has an ultimate bearing capacity of 300 kPa, and excludes:

- Potentially compressible ground
- Expansive soils
- Ground which could foreseeably experience movement of 25 mm or greater for any reason

The Department of Building and Housing (DBH) has included liquefiable soils in the ground conditions, for which NZS 3604 is not applicable. On the basis of regional geology, and inspection pit investigations, the site soils, other than the topsoil, are considered unlikely to be expansive or compressible.

The thick sequence of gravelly soils (Q1a Alluvium), which underlies the site from depths of 0.6m to 1.8m, is considered to meet the bearing capacity criteria for "good ground" according to NZS 3604.

The topsoil is not a suitable bearing stratum for dwelling foundations and should be removed from the building platform pre-construction.

The lots do not appear to be at risk from erosion, falling debris, or slippage. From our assessment it is considered that the site is at minor risk of liquefaction-induced settlement. Accordingly, under Section 106 of the RMA, we consider there to be no geotechnical reasons preventing the subdivision of the property provided the appropriate engineering and construction industry standard measures, and recommendations in this report, are carried out.

5.4 Static Bearing Capacity

NZS 3604 provides a Scala penetrometer test criteria whereby if a certain blow count over a measured depth is met, an ultimate bearing capacity of 300kPa may be assumed (5 blows per 100mm). The gravel dominant Q1a Alluvium is considered to have a geotechnical ultimate bearing capacity of greater than 300 kPa. However, a geotechnical ultimate bearing capacity of 200kPa is considered appropriate for the finer alluvium, which overlies the gravel, due to encountered lateral and vertical variability in the strength of this unit.

5.5 Foundation Development Options

In terms of the DBH Guidelines, where the ultimate bearing capacity meets the 200kPa requirement either enhanced slab solutions or other specific engineering design is applicable. At a conceptual level, enhanced house foundation solutions could comprise the following:

- A shallow concrete slab foundation (thickened over the existing site soils, or built
 over a compacted granular fill raft). It may be possible to excavate and re-compact
 the fine alluvium to construct a densified surface raft. This would reduce the volume
 of imported material but would require more engineering design and quality control.
- A deeper piled foundation founded on the Q1a Alluvium soils (e.g. shallow driven timber piles with an integral concrete raft).

Due to the variability of the depth in the fine alluvium further investigations are recommended at the time of individual building development, as outlined in the DBH Guidelines, to assess the most appropriate and cost-effective solution for each building platform.

5.6 Further Development Considerations

5.6.1 Roads

Roads are not subject to the same design criteria as foundations; however, subgrade layers are required to provide appropriate strength and stiffness for pavement design. Following removal of the topsoil/silt (generally 250mm thick), a design California Bearing Ratio (CBR) of 4% is considered appropriate for the underlying fine alluvium sandy soils.

5.6.2 Services

Buried service trenches are not likely to encounter groundwater at shallow depths throughout the site. However, it is likely that trenching works will likely encounter non-cohesive soils at shallow depth, which may unravel into trenches. It is recommended that buried services be designed detailed with flexibility and resilience in mind.

6.0 Soil Infiltration Testing

We understand that on-site disposal of clean stormwater will be via soakage pits. To assist the preliminary design (by others) of the soakage pits two infiltration tests were completed in TP3 and TP6. The tests were undertaken in general accordance with the Auckland City Soakage Design Manual.

Key points to note about the tests include:

- Each pit was pre-soaked twice prior to the commencement of a falling head percolation test. After pre-soaking, each pit was then re-filled with water to the top of the gravel alluvium and the drop in water recorded at regular intervals.
- The two tests were carried out at different depths below the fine alluvium to assess any change in geological conditions resulting in variability in the permeability rates, and as such the percolation rates calculated range in value. (refer Table 2 and Figure 3, with further calculation details in Appendix D).
- The results were calculated using a formula from Digest 365 of the British Research Establishment, and are limited by the fact that the inspection pits excavated were assumed to be perfectly rectangular and the precision of the measuring devices used (stopwatch and survey staff).

Table 2: Soil infiltration tests summary

Inspection pit number	TP3	TP6
Infiltration test number	. 1	2
Excavated depth	2.7 m	3.2 m
Depth to Q1a Alluvium	1.6 m	1.75 m
Water depth above base of pit, at beginning of test	0.925 m	0.7 m
Plow rate into the pit	1.326 l/s	1.826 l/s
Adopted permeability (of Q1a Alluvium)	2.95 x 10 ⁻⁵ m/s	2.7 x 10 ⁻⁴ m/s
Adopted Infiltration rate	105mm/hr	980mm/hr

Figure 3. Photograph of Infiltration test of gravelly Q1a Alluvium in inspection pit TP3

From the soil infiltration tests undertaken in the (Q1a Ailuvium) gravel we the infiltration rates calculated differ by a factor of 10, and that this is most likely due to differences in the geology between the pit locations. Further testing is advised when during detailed design (by others) of the stormwater system for the subdivision.

7.0 Conclusions

RILEY has completed a geotechnical assessment for the subdivision at 311 Trents Road, Prebbleton. Key points are summarised below:

- 1. The ground has performed well during the recent Canterbury earthquake sequence.
- 2. Ground conditions typically consist of topsoil underlain by generally loose, fine alluvium (silty sand) to a maximum depth of 1.95m over competent gravel with subordinate sand, silt and cobbles. A design groundwater level of 7m is considered appropriate for the site. The encountered ground conditions correspond well with the regional geology from published information.
- 3. The fine alluvium has a variable bearing capacity of approximately 200kPa. The gravel has a geotechnical ultimate bearing capacity of at least 300kPa, and is a suitable stratum for any foundation type. Specific investigations for each individual development are recommended in line with the DBH Guidelines.
- 4. The proposed subdivision is considered acceptable from a geotechnical perspective provided the recommendations outlined in this report are followed.
- 5. Based on the interpreted geology and design groundwater conditions, the site is considered to have a minor risk of liquefaction from future design earthquake events. The risk of liquefaction-induced ground damage is consistent with a TC1 zoning.
- Inspections of ground conditions during the construction phase should be undertaken in accordance with accepted practice. RILEY should be informed if there are any changes from the conditions described in this report.

8.0 Limitation

This report has been prepared solely for the benefit of David and Sue Anderson as our clients, with respect to the brief provided. The reliance by other parties on the information or opinions contained in the report shall, without our prior review and agreement in writing, be at such parties' sole risk.

Recommendations and opinions in this report are based on data from limited test positions. The nature and continuity of subsoil conditions away from the test positions are inferred, and it must be appreciated that actual conditions could vary considerably from the assumed model.

During excavation and construction the site should be examined by an engineer or engineering geologist competent to judge whether the exposed subsoils are compatible with the inferred conditions on which the report has been based. It is possible that the nature of the exposed subsoils may require further investigation and the modification of the design based upon this report.

Riley Consultants Ltd would be pleased to provide this service to David and Sue Anderson and believes the project would benefit from such continuity. In any event, it is essential Riley Consultants Ltd is contacted if there is any variation in subsoil conditions from those described in the report as it may affect the design parameters recommended in the report.
